TITLE: On the problem of improving ferrotitanium melting techniques

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 6, 1962, 23 - 24, abstract
6V161 ("Metallurg. i khim. prom-st' Kazakhstana. Nauchno-tekhn. sb.",
1961, no. 5 (15) 12- 17)

TEXT: During the melting of Fe-Ti the equilibrium of the Ti reduction reaction is established at a high concentration of Al in the heat and of TiO in the slag, usually bound with Al_2O_3 . A higher lime amount in the charge will cause transition of the slag TiO into a free state and simultaneously reduce the melting temperature of the slag; consequently, conditions of metal regulus deposition will be improved. A certain increase of the Al amount in the charge will make it possible to reduce the free TiO in the slag. To check these conditions experimental heats were produced at the Aktyubinsk ferroalloy plant. The results showed the expediency of raising the lime content in the charge by 20% and of Al by about 3% against the usual amounts. In the 45 experimental heats the average

On the problem of...

Al consumption was 479 kg/t, and Ti extraction was 72.3%. A number of 83 experimental heats were produced with the use of an Al block for the deposition of reguli; 83 heats were produced with a mixture of Al and Fe-Si for the same purpose. The heats proved that the reduction of slag oxides occurs on account of Al; Fe-Si is melted and passes into the metal. In heats without Fe-Si, the Si content decreased from 5.27 to 4.88% and the Ti extraction remained on the same level (72.2%). Simultaneously the yield of Ti-O grade alloy increased from 3.6 to 6%.

The Determination of Small Quantities of Arsenic in Metals and Ores by Precipitation with Sodium Hypophosphite. S. Yu. Fainberg and L. B. Gintzburg (Zavodskaya Lab. (Works' Laboratory), 1932, (7), 23-29, C. Abn., 1933, 20, 6328). [In Russian.] Detailed instructions are given for a method very similar to that of Evans (*J. Ind. Metals*, 1929, 42, 534). The determination of As in non-ferrous metals (Cu, Ni, Cd, Bi, Pb, Sn, and Sb), in alloys (brass, bronze, and bearing alloys containing Sn and Pb), and in ores is described. S. G.

Simple determination of lead in lead-zinc ores, concentrates and their products Yu. Yu. Lur'e and I. B. Ginzburg. *Zhurnal Anal. Khim.* 6, 290 (1937). (1) Heat 0.5-1.0 g. of sample with 10 ml. of concd. HCl and with 5 ml. of concd. HNO₃. Dil. the resulting soln. with 50 ml. of water and 5 ml. HCl. Boil, filter and allow to cool. To the cold soln. add 0.5-1.0 g. tartaric acid, a slight excess of NH₄OH and 5 ml. of AcOH. Dil. to 100 ml. and ppt. PbCrO₄ with 10 ml. of 5% K₂Cr₂O₇. Filter and wash the PbCrO₄ with dil. AcOH. Dissolve the ppt. in a mixt. of 1 g. satd. NaCl soln., 15 ml. water and 100 ml. of concd. HCl. Dil. the filtrate and det. the Cr iodometrically. (2) To the soln. prepd. as in (1) add a slight excess of NH₃ and dissolve any ppt. of Fe(OH)₃ by adding 10 ml. of 3 N HNO₃. Dil. to 250 ml. and ppt. PbCrO₄ by means of 10 ml. of (NH₄)₂CrO₄. Filter, wash and dissolve as in (1). To this soln. add water to make 200 ml., add 2 ml. H₂SO₄ and a measured vol. of 0.1 N FeSO₄. Titrate the excess Fe²⁺ with standard K₂Cr₂O₇ soln. with diphenylamine as internal indicator. (3) Dissolve the sample as in (1) but with the omission of the final HCl treatment. Ppt. the Pb as PbCrO₄ by means of a measured vol. of 0.1 N K₂Cr₂O₇, filter and take an aliquot part of the filtrate for the detn. of the excess K₂Cr₂O₇, finishing the analysis as in (2). Chan. Blanc

Preparation of copper and nickel in lead-
ing amount of metallic lead oxide. J. J. LORAN
and G. J. CAMPBELL, *Anal. Lab.*, 1934, 7, 11-15).—
Copper was prepared in HCl, the solution is
carefully washed and the residue extracted with
1% HNO₃. The residue was dissolved directly in
HNO₃, the solution was washed, boiled repeatedly
with 10% potassium permanganate solution with aq.
NH₃, and then extracted with a 10% aq. NH₃. It
is added to the solution of Cu until there are no color,
when a precipitate consisting of antimony Pt-gases
cathode in HNO₃ from the solutions at 85-90°.
30-40% of the total weight of the gas removed and
intended to be used for Pt, Au, Os in 2%; AcOH, at
50-60° for 1 min. The Pt cathode is then washed with
NaOH, dried at 100-105°, and weighed; gain in wt.
equals 34.1% Cu content of the sample. The deposit
is then dissolved in HNO₃ and Bi determined by
known methods; Os is given by difference. R. T.

Utilization of Heat in Glass-Melting Furnaces. (In Russian.) L. B. Ginzburg. *Glass and Ceramic Industry* (U.S.S.R.), No. 3, 1947, p. 9-13.

Extensive tables and charts correlate the work of various investigators on the above subject.

2163. Modification of the thiocyanate method of determining molybdenum. L. B. Ginsburg and J. J. Lurie (Zaved. Lab., 1948, 14, 838-848; *Metall. Zh.*, 1949, 18, 793). The sample (0.1-0.8 g) is dissolved in aqua regia, 10 ml of H_2SO_4 (1:1) are added and the solution is heated until SO_2 is evolved. The cooled solution is diluted with 30-40 ml. of water, boiled to dissolve the residue, transferred to a 100-ml. flask, and made up to the mark with water. An aliquot part of the solution containing 0.4-0.8 mg. of Mo is placed in a measuring cylinder, and 38 ml. of HCl (1:3), 30 ml. of 20% aq. thiocyanate, 1 g. of KI , and 1 ml. of 1% aq. Na_2SO_4 are added, with shaking after each addition. The solution is made up to the 60-ml. mark with HCl (1:3) and placed in a colorimeter for 10 min., using the green-light filter No. 54 (max. transmission 520-560 m μ). The Mo content is determined from a calibration curve obtained by measuring the light-absorption of solutions of known concentration under identical conditions. R. B. GINSBURG

*Investigation of Colorimetric Methods of Determining Bismuth. Yu. Yu. Lur'e and L. R. Ginzburg (*Zaved. Lab.*, 1949, 15, (1), 21-30).—[In Russian]. A comparison is made of the KI, rhodamide, and thiourea methods of colorimetric quantitative determination of Bi in the presence of Pb, Sb, Sn, As, Cu, and Fe. The first method is described briefly, the two others in detail. A violet-light filter with max. permeability in the range 400-470 mμ, corresponding to max. extinction by Bi-complexes, is used in all three methods, the formation of coloured Bi-complexes occurs in 1-2N-H₂SO₄, 1-3.5N-H₂SO₄, and 0.4-1.2N-HNO₃, respectively. The sensitivities of the three methods decrease in the order 8-11-22 · 10⁻⁴ γ/cm.², where γ is the concentration (mg./l.) · thickness of colorimetric layer (cm.); the ranges of error · 1% are 2.6-13.3, 6-20, and 3.2-20 γ cm.², respectively, so that for low concentrations only the KI method gives sufficient precision, and for high concentrations only the other two. Coloration occurs in all cases immediately upon addition of the complex forming reagent and remains stable for 3-4 hr in the KI, and for 90 min. in the other two methods. Several ways of preventing the formation and/or of taking into account the effects of coloured complexes by Sb, Pb, As, are mentioned, and the analytical techniques are described in detail. The KI method is the most precise of the three and has the widest range of application, but if Pb is present in large quantities only the thiourea method can be used.—T. O. L.

Title : Experiment of Application of Mathematical Statistical Method to Establish Norms of Permissible Discrepancies of Assay Results.

Orig Pub : Zavod. Laboratoriya, 1956, 22, No 10, 1157-1166.

Abstract : The method of mathematical statistics was used to develop the norms of permissible discrepancies at the assaying of products of the Pb, Zn and Cu industries. 5,820 assays were made for the Pb and Zn industries and 9,140 assays were made for the Cu industry. The following formulae were used for the mathematical treatment of the results: $\bar{x} = (x_1 + x_2 + x_3 + \dots + x_n)/n$; $S = \sqrt{[(x_1 - \bar{x})^2 + (x_2 - \bar{x})^2 + \dots + (x_n - \bar{x})^2]/n}$; σ_p (relative) = 100 σ_p %. It was established that the reproduction of results depended little on the assayed

product and varies depending on the contents of the determined component. The degree of error distribution followed the law of the normal distribution; 70% of the results differ < 2 from a (arithmetical mean) of the series. The value 2 was proposed as the norm of the permissible discrepancy. It was proved statistically that the ferrocyanide method with the use of an exterior indicator is not applicable at < 1% of Zn; the polarographic method gives better results. The method of the determination of Al_2O_3 by difference gives badly reproducible and often wrong results; it is recommended to use direct methods (weight determination in the form of oxide of phosphate).

TITLE: Colorimetric Methods for the Determination of Trace Elements in the Dusts of the Nonferrous Metals Industry (Kolorimetricheskiye metody opredeleniya rasseyannykh elementov v pylyakh proizvodstva tsvetnykh metallov)

PERIODICAL: Izv. AN KazSSR, ser. khim. 1957, Nr 1, pp 94-98

ABSTRACT: Methods were developed for the determination of trace elements using small specimens containing thousandths and hundredths of one per cent of the element sought with a 10 - 15% relative error. The determination of Tl is based on the reaction of $TlCl_4$ with methyl violet. The complex compound formed is dissolved in toluene imparting to it a blue-violet color. The maximum absorption is 530 - 620 m μ . 10 cc of toluene extract up to 50 γ of Tl from 25 cc of solution. Sb impedes the analysis. The determination of Ge is based on the reaction with phenylfluorone in an acid medium. Ge^{4+} forms a red compound. The maximum absorption is 490 - 530 m μ . Many elements, especially Sb, impede the

Card 1/2

Colorimetric Methods for the Determination of Trace Elements (cont.)

analysis. Ge is first distilled off in the form of its tetrachloride in the presence of KMnO_4 and Na_2SO_3 . The weighed test sample is decomposed by fusion with Na_2O_2 in Ni or Fe crucibles. Within the range of 1 - 25 γ in 25 cc, Ge can be determined colorimetrically. The determination of In and Ga is based on the fact that solutions of oxiquinolates of In and Ge in chloroform are fluorescent under ultraviolet rays. To separate Ge it is extracted with ether from a 6N HCl solution in the presence of TiCl_3 . To separate In its bromide is extracted with ether after which it is determined by ion-exchange chromatography with the SBS type cationite. The sensitivity of the determination of Ga is 0.1 γ , that of the determination of In is 0.5 γ in 3 cc of chloroform. The determination of Re is based on the formation of a complex compound of Re with a thiocyanate in a hydrochloric-acid solution in the presence of SnCl_2 . Mo impedes this analysis. The determination of 5 γ Re in a 5N HCl solution is feasible in the presence of 50 - 60 γ Mo by measuring its optical density 30 min after the addition of the reagent.

TITLE:

Determination of Thallium From the Absorption of the Solution
of Its Chloride in Ultraviolet

PERIODICAL:

Zavodskaya laboratoriya, 1959, Vol 25, Nr 10, pp 1157-1162 (USSR)

ABSTRACT:

By means of the spectrophotometer of type SF-4 (with hydrogen lamp), experiments were carried out concerning the applicability of the chlorides and bromides of indium, gallium and thallium to the absorptiometric determination of these elements in nonferrous metal products. The chlorides and bromides of indium and gallium cannot be used for spectrophotometric determinations of these elements since no light absorption occurs in these solutions up to a concentration of elements of about 500 mg/l. In the chlorine and bromine compounds of thallium, a light absorption in the ultraviolet part of the spectrum, in hydrochloric-acid solutions, was ascertained for both forms of valence (Tl^+ and Tl^{3+}) (Figs 1, 2). In 6n HCl, the absorption maximum of $TlCl$ and $TlCl_3$ lies at a wave length of 244-246 m μ . The molar absorption coefficients of $TlBr_3$ and $TlCl_3$ nearly agree, and are 3 times larger than those of $TlBr$

and $TiCl_3$ (Table 1). The chlorides and bromides of Bi, Sb, Sn, Cu, Pb, and Fe also absorb the light in the ultraviolet range so that the thallium has to be extracted before a spectrophotometric determination with ether from a hydrobromic-acid solution of the sample. Experiments concerning the oxidation of thallium into the trivalent form were carried out with bromine, hydrogen peroxide, potassium persulphate, and potassium nitrite, while formalin, phenol and urea were tested for the destruction of the excess reducing agent. Phenol proved to be most favorable. The analytical results obtained by two methods from the chloride- and bromide compounds are in good agreement (Table 2); it is, however, recommended to carry out the determination by use of the chloride compound since the "zero solution" has no light absorption in this case. A course of analysis is indicated. The method was tested by dust samples of the lead-zinc production. The method permits thallium determinations from a sample of 1 g with a content of more than 0.005% Tl. There are 3 figures, 2 tables, and 1 Soviet reference.

TITLE: Effect of lubricating oil on scale formation in Diesel engines

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 19, 1961, 424, abstract
19M193 (Inform. sb. Tsentr. n.-i. in-t morek. flota, no. 47.
1960, 49 - 57)

TEXT: The cylinder emulsion oils synthesized at the VNIINP were tested in a two-cylinder, two-stroke engine type 24016.5/20 (2 DSP 16.5/20), 50 HP at 750 rpm, operating with sulfur fuel (mixture of 65 % export mazout, trademark "Ю" ("Yu") and 35 % Diesel fuel with 2.53 % sulfur). The test showed that the oil samples produced in the USSR have properties preventing scale formation and guaranteeing the purity of the Diesel engine piston group even during operation with highly sulfurous fuels. This is mainly due to the presence of a considerable amount of alkaline additives in aqueous phase neutralizing the primary oxydation products of the oil and preventing the formation of tars and other polymeric products. ✓B

S/05:001/000/019/069/085

Effect of lubricating oil on scale formation. B:17/B110

Emulsion oils are recommended for lubricating low-speed Diesel engine cylinders particularly when, during the use of customary cylinder oils (motor oil, automobile lubricant AK 15 (AK 15)), the cylinders are soiled by scale and varnish. It is pointed out that in a Diesel engine comprising a precombustion chamber the thickness of the scale layer in the combustion chamber does not depend on the kind of fuel and oil used. ✓B

TITLE:

Shcherbakov, V. M., Mazur, S. V., Ginzburg, L. N.
Strength properties of glass plastics. Strength and
elasticity of glass plastics under static and impulsive loads

PERIODICAL: Plasticheskiye massy, no. 4, 1962, 33-45

TEXT: The results of tensile, and static and impact bending tests are given, together with analytical methods of determining ultimate tensile stress and the modulus of elasticity. Epoxy phenol resin shows least shrinkage on hardening, good adhesion on glass cloth, no hair line cracks, and low internal stresses. Good tensile strength was found in plastics with satin or twisted glass cloth T_1 (T_1). This is because the filler is better impregnated and the bond between the layers of glass cloth is strengthened. Tensile rupture of glass plastics takes place in three stages: (1) the bond between resin and glass filler is destroyed, and spalling begins at the resin-glass interface, (2) the resin starts peeling off, and the filler takes over the whole load, (3) the glass cloth is

Card 1/5

5/10/1/02/000/004/010/017
 B110/B136

Strength properties of glass...

ruptured. $\sigma F = \sigma_g F_g + \sigma_r F_r$ holds, where σ = stress in the glass plastic,
 σ_g = stress in the glass filler, σ_r = stress in the resin, F = total
 cross section area, F_g = area of glass filler cross section, F_r = area of
 resin cross section. The ultimate tensile strength (UTS) is

$$\sigma = \sigma_{cu} + \gamma_{cu} \frac{0.5(\beta_{cr} - \sigma_{cu}) - \sigma_{cu}}{R} \quad (5)$$

$$\gamma_{cu} + \gamma_{cr} - R$$

where σ = UTS of glass plastic, σ_{cu} = UTS of resin, σ_{cr} = UTS of
 elementary glass fiber, α = resin content by weight, β = strength
 utilization factor of elementary glass fiber, γ_{cu} = specific gravity of
 hardened resin, γ_{cr} = specific gravity of glass fiber ($\sim 2.5-2.6$). For
 glass plastics reinforced with unidirectional fiber:

$$\sigma = \frac{\gamma_{cu}(\beta_{cr} - \sigma_{cu})}{R} + \sigma_{cu} \quad (6)$$

$$\gamma_{cu} + \gamma_{cr} - R$$

Strength properties of glass...

S/191/62/000/004/010/017
B110/B135

Equations (5) and (6) are however, only approximate, as a lot of factors influencing strength are not taken into account. In glass plastics with satin woven glass cloth, the different layers are well interlinked, load is distributed between resin and filler, and the damaging glass-glass contact is avoided. Production under pressure gives 10-25 % higher bending strength in phenol and polyester resins than does vacuum molding, and 40-55 % in epoxy phenol plastics. Resin content has a decisive influence on bending strength of glass plastics: at 14.6 % UTS in bending was 162 kg/cm², and at 28.8 %, 1645 kg/cm². In static bending tests of epoxy phenol glass plastics, no fracture occurred at the interface at 150-200 kg/cm². The UTS in bending is

$$\sigma = 1/I \sum_{i=1}^n \sigma_i I_i,$$

where σ_i denotes the stress in the components of the glass plastic and I_i are the moments of inertia of their cross sections. Although the UTS of the best glass plastics is almost as high as that of steel, the modulus of elasticity is only 1/10.

Strength properties of glass...

S/191/62/000/004/C10/C17
B110/B178

$$E = 1/F \sum_{i=1}^n E_i F_i$$

defines the modulus of elasticity, F denotes cross sectional area of the test piece, F_i the cross sectional area of the individual components, E_i their moduli of elasticity. The modulus of elasticity and impact strength in bending (pendulum velocity = 3.5 m/sec) increase with the thickness of the glass cloth. Good values were obtained with braided small-cell cloth and with satin weave. The deformation of glass plastics obeys Hook's law right up to rupture. Quantitative estimates of strength and deformation were made to assess suitability for engineering purposes. Approximate values for the maximum dynamic deflection f_d and impact toughness in bending strength σ_d are found from the amount of work dissipated in destruction. $f_d = f_{st} + \sqrt{f_{st}^2 + 2hf_{st}}$, where $f_{st} = Pl^3/48EI$ = static deflection under load P and $\sigma_d = 3\sqrt{2AE/b\delta l}$, where E is the modulus of elasticity, A is the work of destruction, δ is sample thickness, b is

Ferrous pigments from marsh ore. A. V. Pankilov and L. N. Ginzburg. *J. Applied Chem. (U.S.S.R.)* 19, 1118 (1946) (in Russian). Marsh ore was found suitable for use as raw material for Fe minimum and maximum type pigments. The manufacturing process consists in classification by Fe content (samples with higher Fe are dished and banded) and calcining and grinding. The ore gave no definite x-ray diagrams, γ Fe α_1 is obtained around 500° and is converted into α Fe α_2 at 735-750°. The influence of calcining between 500° and 1000° for 1-4 hrs on d, particle size, oil consumption, and covering power was investigated. (U.S.S.R.)

"Stability of Astronomical Systems," D. D. Ivanenko, A. M. Brodskiy, L. P. Ginzburg,
Moscow State U imeni Lomonosov

"Dok Ak Nauk SSSR" Vol LXXX, No 4, pp 565-567

The discussion of Einstein's gravitational field can in a linear approximation be reduced by analogy to a discussion of other wave fields. In this report the authors extend this analogy and introduce the concept of temp and thermal radiation of a weak gravitational field. The derived representations are then applied for the purpose of clarifying problems of stability of certain astronomical systems. Crit temps are found for the various planets and the sun. Submitted 4 Aug 51 by Acad V. G. Fesenkov.
